

# BIT PRECISION-DECLARATION

Lecture – 5-Data type-Part2

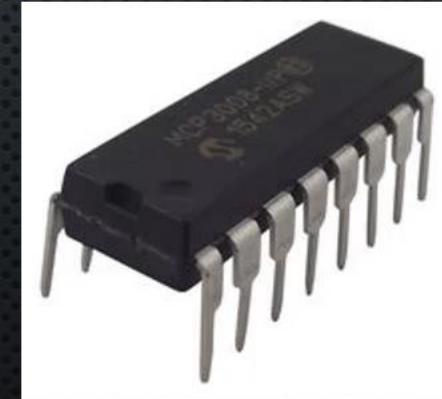

# BIT PRECISION

## Instruction Coding

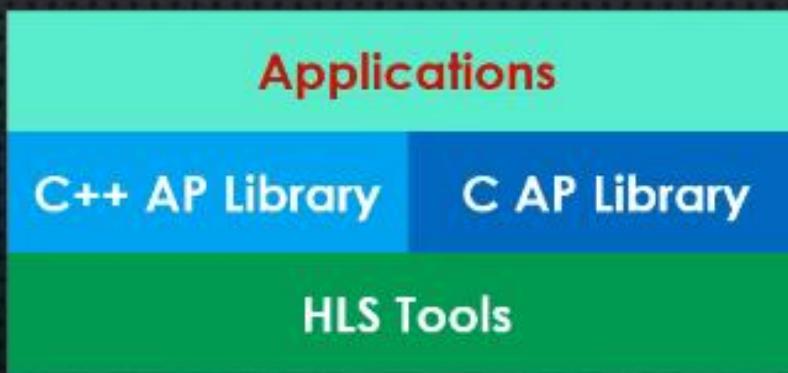

Analogue to Digital Converter, 10 bit,

# BIT PRECISION IN HLS

Arbitrary Precision Data Type

Simulation  
Synthesis

# BIT PRECISION IN HLS LIBRARY

- ❖ C++ is a template class
- ❖ `#include <ap_int.h>`
- ❖ `ap_[u]int<w>`

integer precision

fixed-point precision

C++ AP Library

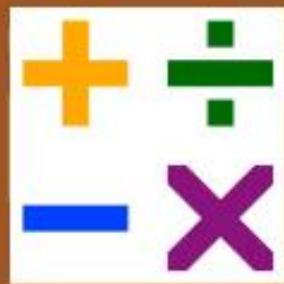

`ap_int<w>` ..... signed integer  
`ap_uint<w>` ..... unsigned integer

Examples

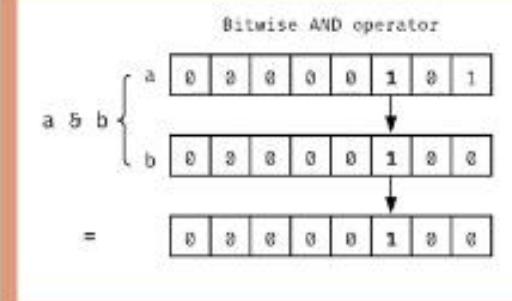

```
#include "ap_int.h"  
ap_int<5> a;  
ap_uint<11> b;
```

# AP\_[U]INT TEMPLATE CLASS

## Arithmetic

## Bitwise

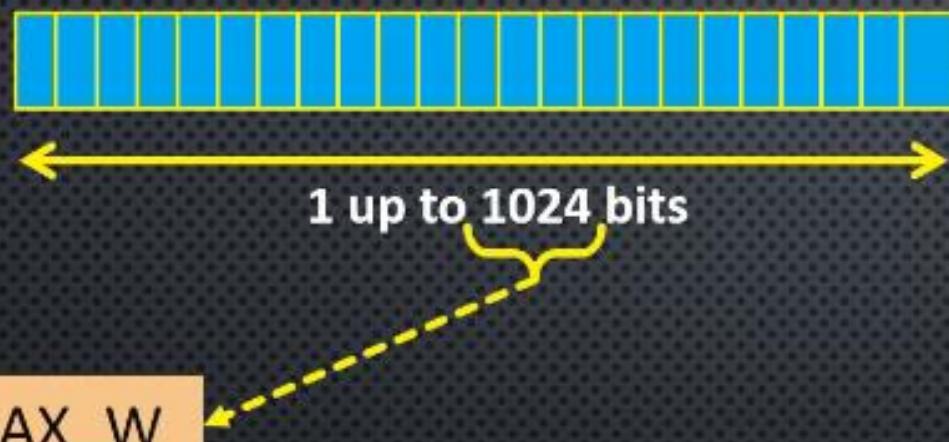

## Logical

Logical AND (&&):

A	B	A&B
T	T	T
T	F	F
F	T	F
F	F	F

# ARBITRARY BIT-WIDTHS

AP\_INT\_MAX\_W

a positive integer value less than or equal to  
32768 before inclusion of the *ap\_int.h* header  
file.

## Example

```
#define AP_INT_MAX_W 8192  
  
#include "ap_int.h"  
  
ap_int<8192> wide_a;
```

# ASSIGNMENT Q

**What is the maximum default bit-width of an arbitrary-precision integer data type in Vivado-HLS?**

# BIT PRECISION-INITIALIZING

Lecture – 4-Data type

# INITIALIZATION

```
ap_int<17> a = 0x17e;
```

a 0 0 0 0 0 0 0 0 1 0 1 1 1 1 1 1 1 0

```
ap_uint<57> b = 0xef42ed12cf72abULL;
```

# INITIALIZATION (CONSTRUCTOR)

**ap\_[u]int<w> a = ap\_[u]int<w>(string, radix);**

**ap\_[u]int<w> a (string, radix);**

```
ap_int<41> a1 = 04017; //  
ap_int<41> a1 = ap_int<41>("4017", 8);  
ap_int<41> a1 = ap_int<41>("0o4017");  
ap_int<41> a1 = ap_int<41>("0o4017", 8);
```

```
ap_int<763> a1 = ap_int<763>("401740174017401740174017", 16);  
ap_int<763> a1 = ap_int<763>("0x401740174017401740174017");  
ap_int<763> a1 = ap_int<763>("0x401740174017401740174017", 16);
```

# CONSOLE I/O(PRINTING)

```
ap_int<41> a = ap_int<41>("4017", 8);  
std::cout << " a = " << a << std::endl;
```

**a = 2063**

```
ap_int< 763 > b = ap_int< 763 >("0x401740174017401740174017");  
std::cout << " b = " << b << std::endl;
```

**b = 19835148582765468633513017367**

# CONSOLE I/O(PRINTING)

```
ap_int< 763 > b = ap_int< 763 >("0x401740174017401740174017");  
  
std::cout << " b = " << std::oct << b << std::endl;

b = 19835148582765468633513017367  
b = 0x0401740174017401740174017
```

# SUMMARY

- ❖ We can use the C/C++ initialisation to assign a value to a declared variable with length less than 64 bits.
- ❖ For arbitrary precision data types, more than 64 bits class constructors can be used for initialisation.

# ASSIGNMENT Q

**Declare a 362-bit width variable of unsigned integer type and initialise that with a value that set all bits to one.**

# BIT PRECISION-ASSIGNMENT

Lecture – 4-Data type

# ASSIGNMENT

```
ap_int<17> a = 0x17e;
```

a 0 0 0 0 0 0 0 0 1 0 1 1 1 1 1 1 0

**Assignment operators:** =, +=, -=, \*=, /=, %=, <<=, >>=, &=, ^=, |=

```
ap_int<17> c;
```

```
c = a;
```

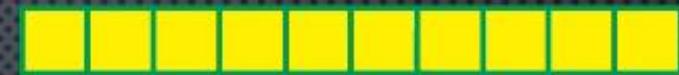

c 0 0 0 0 0 0 0 0 1 0 1 1 1 1 1 1 0

```
ap_int<17> c(a);
```

# NARROWER OR WIDER ASSIGNMENT

```
ap_int<10> a;  
ap_uint<17> b;  
ap_int<8> c;
```

a

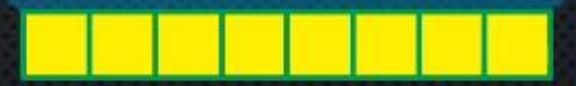

b

**b = a;**  
Wider Assignment

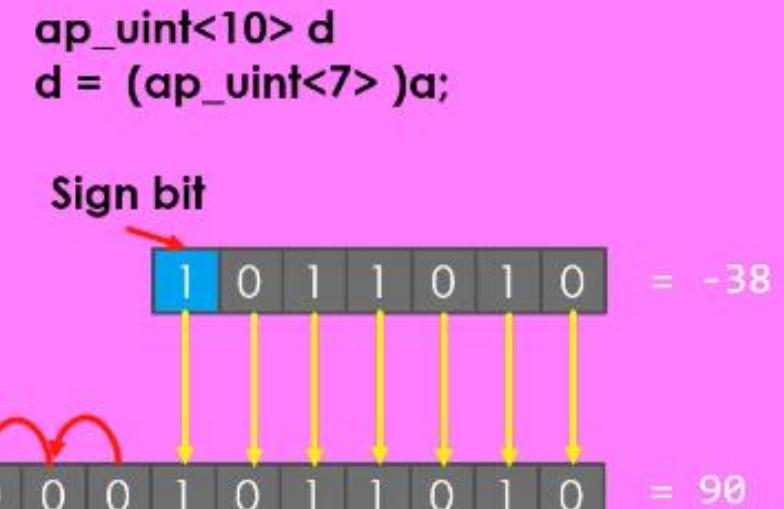

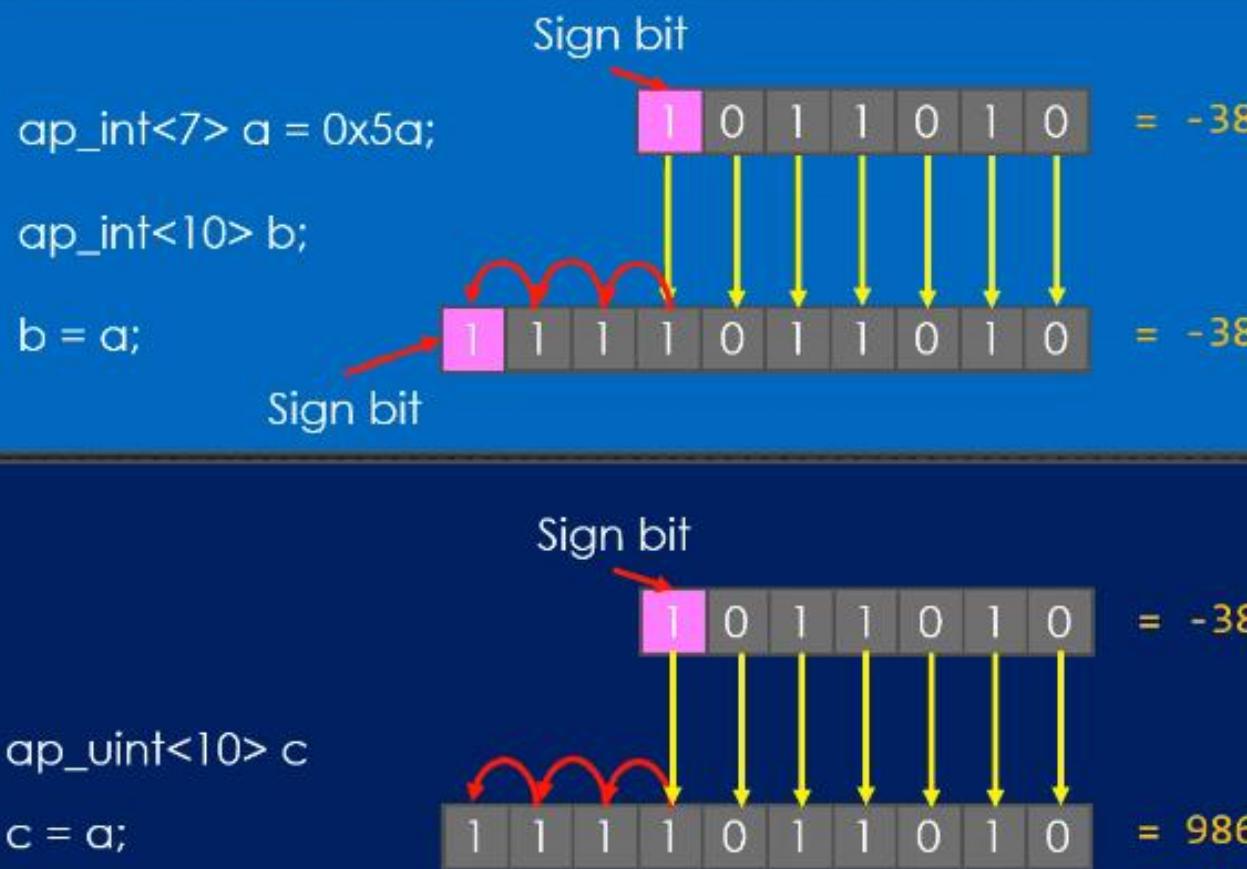

c

**c = b;**  
Narrower Assignment

Sign-Extension  
Zero-Extension  
Truncation

# SIGN EXTENSION

# ZERO EXTENSION

```
ap_uint<7> a = 0x5a;
```

```
ap_uint<10> f
```

```
f = a;
```

1 0 1 1 0 1 0  
= 90

A binary number represented by seven gray squares. The first square contains a '1'. The next six squares contain '0's. Yellow arrows point from each square to the right, indicating the value of each bit.

0 0 0 1 0 1 1 0 1 0  
= 90

A binary number represented by ten gray squares. The first three squares contain '0's. The next seven squares contain '1's. Yellow arrows point from each square to the right, indicating the value of each bit.

```
ap_int<10> g
```

```
g = a;
```

Sign bit

1 0 1 1 0 1 0  
= 90

A binary number represented by seven gray squares. The first square contains a '1'. The next six squares contain '0's. Yellow arrows point from each square to the right, indicating the value of each bit.

0 0 0 1 0 1 1 0 1 0  
= 90

A binary number represented by ten gray squares. The first three squares contain '0's. The next seven squares contain '1's. Yellow arrows point from each square to the right, indicating the value of each bit.

```
ap_int<10> h;  
h = (ap_int<7>)a;
```

1 0 1 1 0 1 0  
= 90

A binary number represented by seven gray squares. The first square contains a '1'. The next six squares contain '0's. Yellow arrows point from each square to the right, indicating the value of each bit.

1 1 1 1 0 1 1 0 1 0  
= -38

A binary number represented by ten gray squares. The first four squares contain '1's. The next six squares contain '0's. Yellow arrows point from each square to the right, indicating the value of each bit.

Sign bit

# TRUNCATION

```
ap_int<10> l = 0x21a;  
ap_int<7> m ;  
m = l;
```

Sign bit

= -486

= 26

```
ap_uint<10> n = 0x21a;  
ap_uint<7> k ;  
k = n;
```

= 538

= 26

# SUMMARY

- ❖ There are two different cases if we assign two variables that their bit-widths are not the same: wider assignment and narrower assignment.
- ❖ There are three techniques are introduced to handle these situations which are
  - Sign-extension
  - Zero-extension
  - And truncation.

# ASSIGNMENT Q

**What are the values of all variables in this code after execution?**

# BIT PRECISION-PRINT

Lecture – 5-Data type-Part2

# CONSOLE I/O PRINTING

```
#include <iostream>

ap_uint<102> a("10fedcba9876543210u, 16);

std::cout << "a in decimal = " << a << std::endl;

std::cout << "a in octal = "      << std::oct  << a << std::endl;
std::cout << "a in decimal = "      << std::dec  << a << std::endl;
std::cout << "a in hexadecimal = " << std::hex  << a << std::endl;
```

**a in decimal = 313512663723845890576**  
**a in octal = 0o041773345651416625031020**  
**a in decimal = 313512663723845890576**  
**a in hexadecimal = 0x010FEDCBA9876543210**

# USING THE STANDARD C LIBRARY

- ❖ Convert the value to a C++ std::string using the `to_string()`
- ❖ Convert the result to a null-terminated C character string using the `c_str()` method

```
printf("a = %s\n", a.to_string().c_str());    //default radix is 2
printf("a = %s\n", a.to_string(2).c_str());
printf("a = %s\n", a.to_string(8).c_str());
printf("a = %s\n", a.to_string(10).c_str());
```

# SUMMARY

- ❖ Vivado HLS supports printing values that require more than 64-bits to represent.
- ❖ The member function, called *to\_string*, converts the value of an arbitrary precision integer data types into the corresponding C++ string.

# ASSIGNMENT Q

What is the output of this code?

```
...
ap_uint<1024> a("10efffedcba9876543210", 16);
std::cout << "a in octal = "           << std::oct << a << std::endl;
std::cout << "a in decimal = "        << std::dec << a << std::endl;
std::cout << "a in hexadecimal = "    << std::hex << a << std::endl;

printf("a = %s\n", a.to_string().c_str()); //default radix is 2
printf("a = %s\n", a.to_string(2).c_str());
printf("a = %s\n", a.to_string(8).c_str());
printf("a = %s\n", a.to_string(10).c_str());
printf("a = %s\n", a.to_string(16).c_str());
...
```

# BIT PRECISION-BIT LEVEL

Lecture – 5-Data type-Part2

# BIT-LEVEL LENGTH

```
length ()  
ap_int<41> a = 0x23462af;  
int len = a.length();  
len = 41;
```

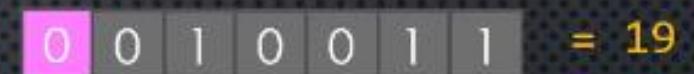

# BIT-LEVEL OPERATIONS

Concatenation: the `concat` member function

```
ap_int<5> b = 0x3;
```

 = 3

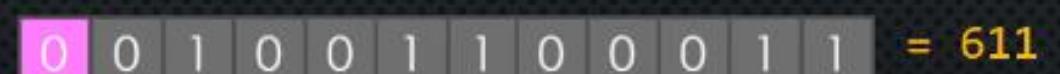

```

```
ap_int<12> r2 = (c, b);
```

 = 611

# BIT SELECTION

The overloaded [] operator

```
ap_uint<7> n = 0x2f;
```

0 1 0 1 1 1 1 = 47

```
int i = 4;
```

```
ap_uint<1> one_bit = n[i];
```

one\_bit = 0

---

```
n[i] = 1;
```

0 1 1 1 1 1 1 = 63

# RANGE SELECTION

Using the **range** member function.

```
ap_uint<4> r;
```

```
ap_uint<9> p = 0xef;
```

0	0	0	0	1	1	1	0	1	1	1	1
---	---	---	---	---	---	---	---	---	---	---	---

 = 239

```
r = p.range(3, 0);
```

1	1	1	1
---	---	---	---

 = 15

```
ap_uint<9> q = 0xBA;
```

0	0	0	0	1	0	1	1	1	0	1
---	---	---	---	---	---	---	---	---	---	---

 = 186

```
p(3,0) = q(3, 0);
```

0	0	0	0	1	1	1	0	1	0	1
---	---	---	---	---	---	---	---	---	---	---

 = 234

```
r = p.range(4, 7);
```

0	1	1	1
---	---	---	---

 = 7

# ASSIGNMENT Q

**What is your suggestion for the bit-width of the r variable and what would be its value after execution of this code snippet?**

```
ap_uint<9> p = 0xef;  
ap_int<5> b = 0x3;
```

```
ap_int<?> r = (p(3,0), b)
```

# BIT PRECISION-BITWISE LOGICAL OPERATORS

Lecture – 5-Data type-Part2

# BITWISE LOGICAL OPERATOR

**Bitwise OR .....**

`ap_int<7> a = 0x2f;`

0 1 0 1 1 1 1

**Bitwise AND .....** &

`ap_int<7> b = 0x31;`

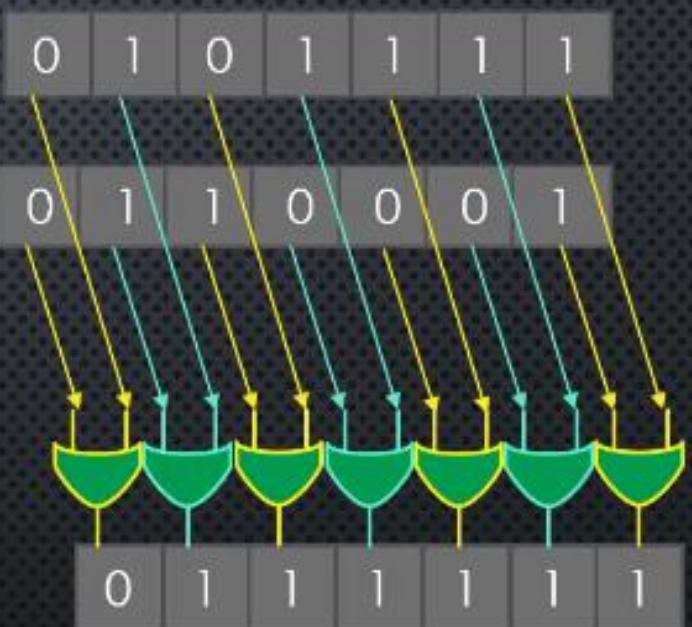

0 1 1 0 0 0 1

**Bitwise XOR .....** ^

**Bitwise Inverse .....** ~

`ap_int<10> c = a | b;`

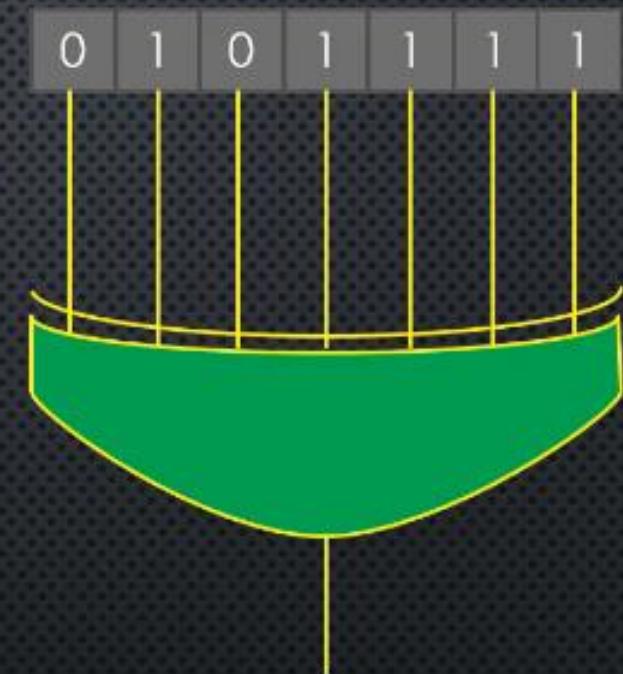

0 1 1 1 1 1 1 1

# REDUCED LOGICAL FUNCTIONS

AND reduce ..... **and\_reduce ()**

ap\_int<7> a = 0x2f;

OR reduce ..... **or\_reduce ()**

XOR reduce ..... **xor\_reduce ()**

NAND reduce ..... **nand\_reduce ()**

NOR reduce ..... **nor\_reduce ()**

XNOR reduce ..... **xnor\_reduce ()**

**XOR reduced = 1**

# BIT REVERSE

Bit Reverse .....reverse()

```
ap_int<7> a = 0x2f;
```

0	1	0	1	1	1	1
---	---	---	---	---	---	---

```
a.reverse();
```

1	1	1	1	0	1	0
---	---	---	---	---	---	---

# TEST/SET/CLEAR

ap\_int<7> a = 0x2f;

0	1	0	1	1	1	1
---	---	---	---	---	---	---

**Test Bit Value** ..... **test (i)** → **bool t = a.test(5); returns True**

**Set Bit Value** ..... **set (i, v), set\_bit(i, v)** → **a.set(5, 0);  
bool t = a.test(5); returns False**

**Set Bit (to 1)** ..... **set (i)** → **a.set(5);  
bool t = a.test(5); returns True**

**Clear Bit (to 0)** ..... **clear (i)** → **a.clear(5);  
bool t = a.test(5); returns False**

# SUMMARY

- ❖ The bitwise logical operators all return a value with a width that is the maximum of the widths of the two operands.
- ❖ Reduced functions apply a given operator to all bits of an arbitrary precision value and return a one-bit result.
- ❖ The bit-reverse member function reverses the bit position of its object value.

# ASSIGNMENT Q

**What is the output of this code snippet running by Vivado-HLS  
in C-Simulation mode?**

```
ap_int<7> a = 0x15;
ap_int<7> b = 0x13;

ap_int<7> c = a | b;
ap_int<7> d = a;
d.reverse();
std::cout << " a = " << a.to_string() << std::endl;
std::cout << " b = " << b.to_string() << std::endl;
std::cout << " c = " << c.to_string() << std::endl;
std::cout << " a xor reduced = " << a.xor_reduce() << std::endl;
std::cout << " d = " << d.to_string() << std::endl;
std::cout << " a.test(5) " << a.test(5) << std::endl;
a.set(5, 0);
std::cout << " a(5) " << a.test(5) << std::endl;
a.set(5);
std::cout << " a(5) " << a.test(5) << std::endl;
a.clear(5);
std::cout << " a(5) " << a.test(5) << std::endl;
```

# MULTIPLEXER

# $N \times 1$ MULTIPLEXER

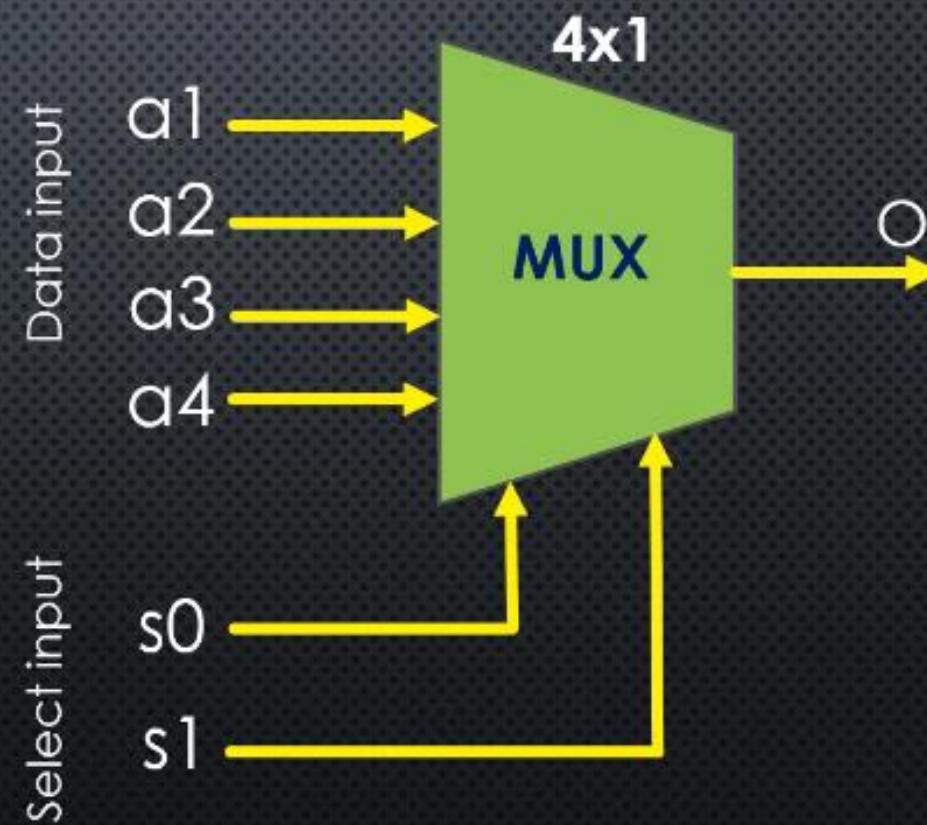

# HOW TO BUILD A MULTIPLEXER WITH LOGIC GATES

# ASSIGNMENT Q

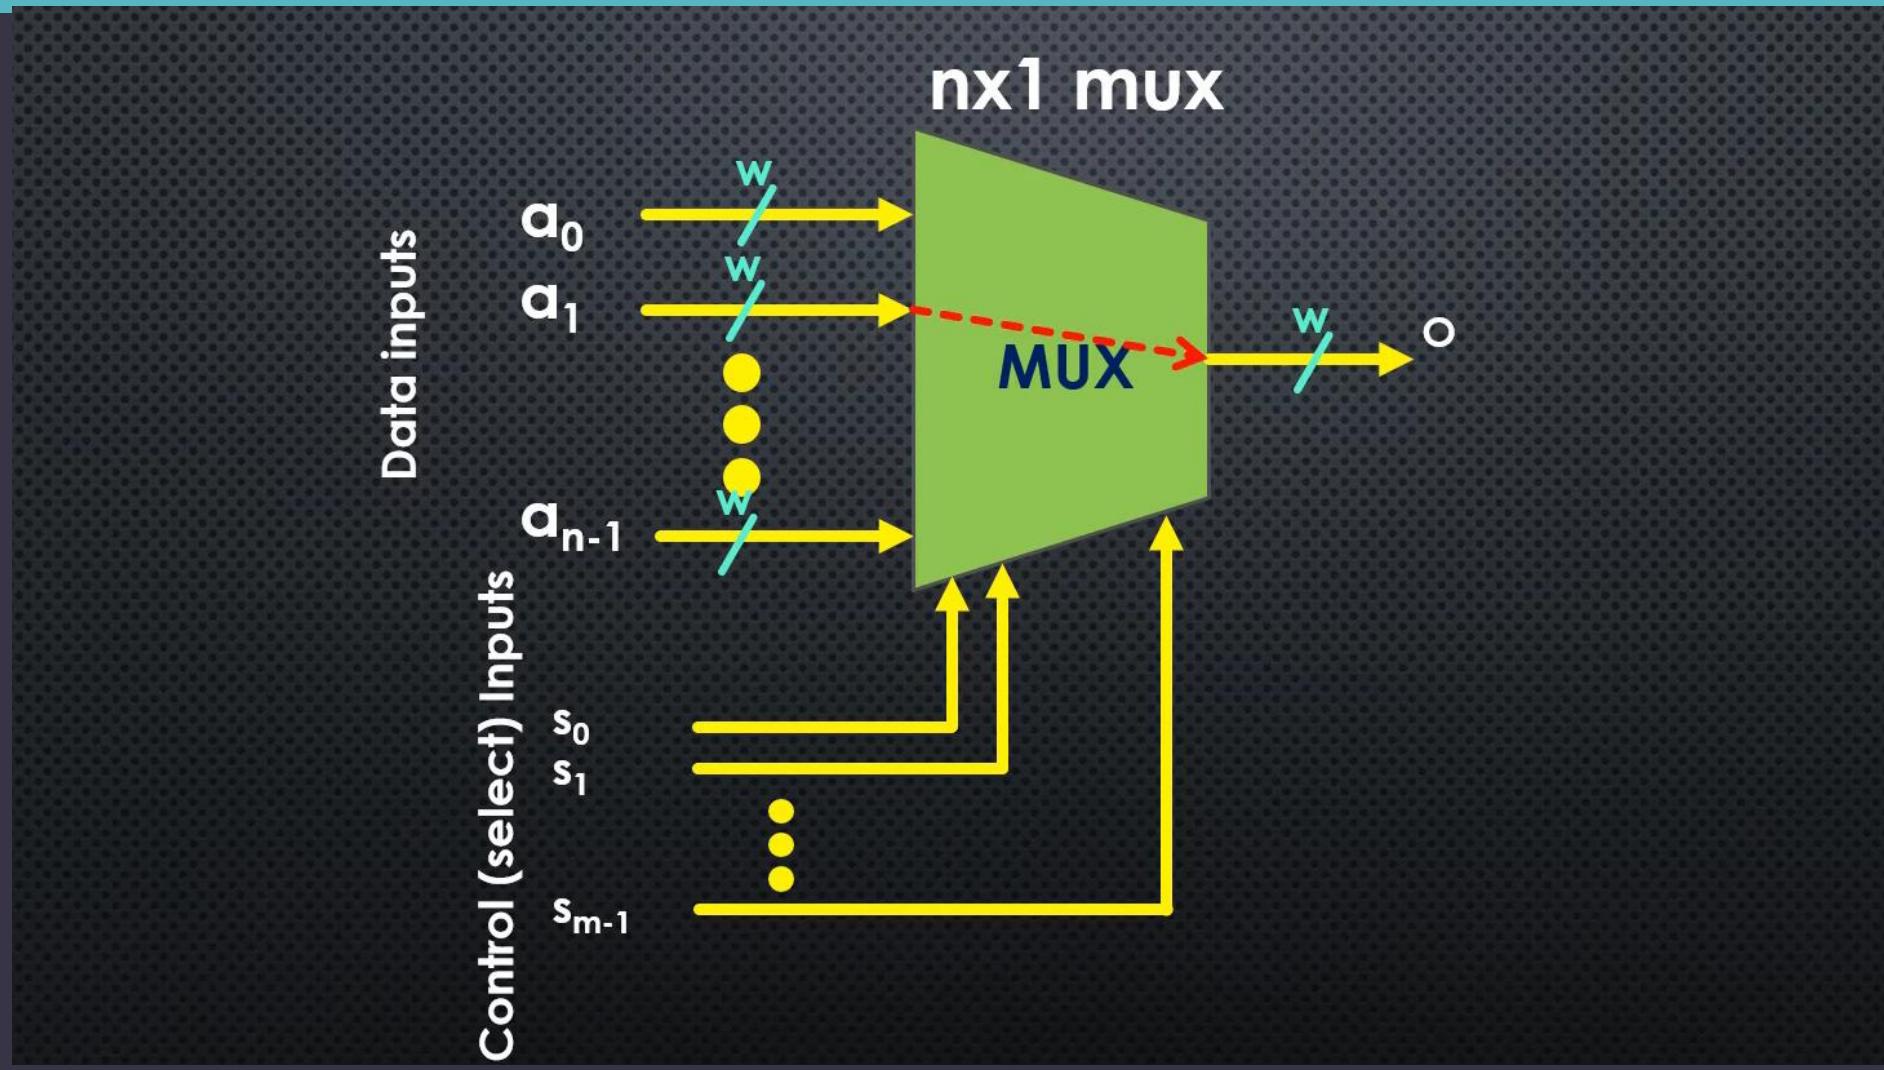

How can a group of basic logic gates implement this 4x1 multiplexer?

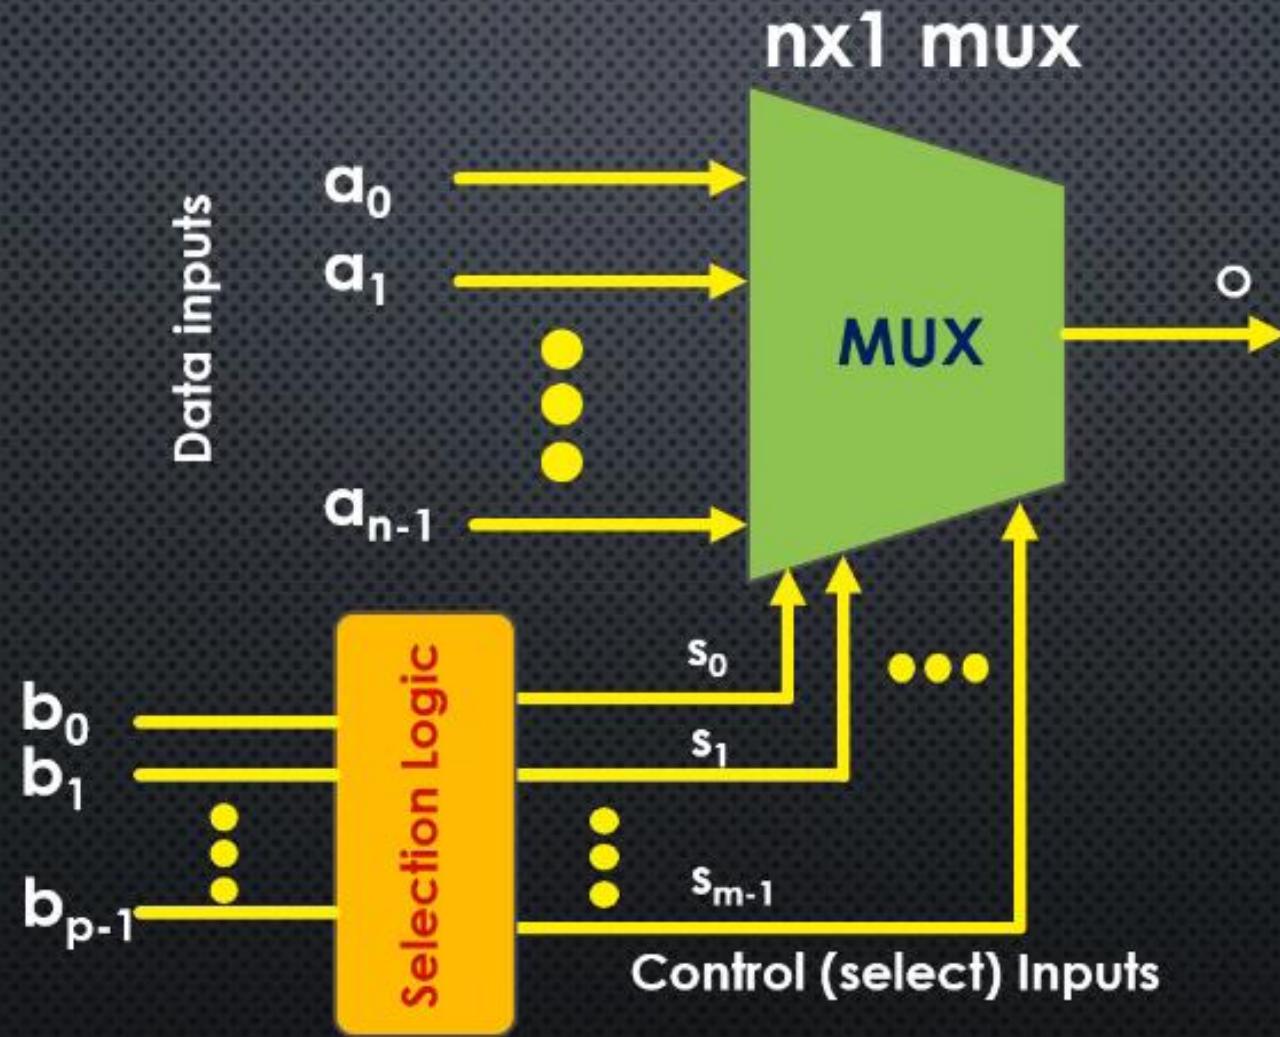

# MULTIPLEXER-GENERAL CASE

Lecture – 4-Data type

# WIDE BIT-WIDTH INPUTS (GENERAL CASE 1)

# COMPLEX DECISION MAKING

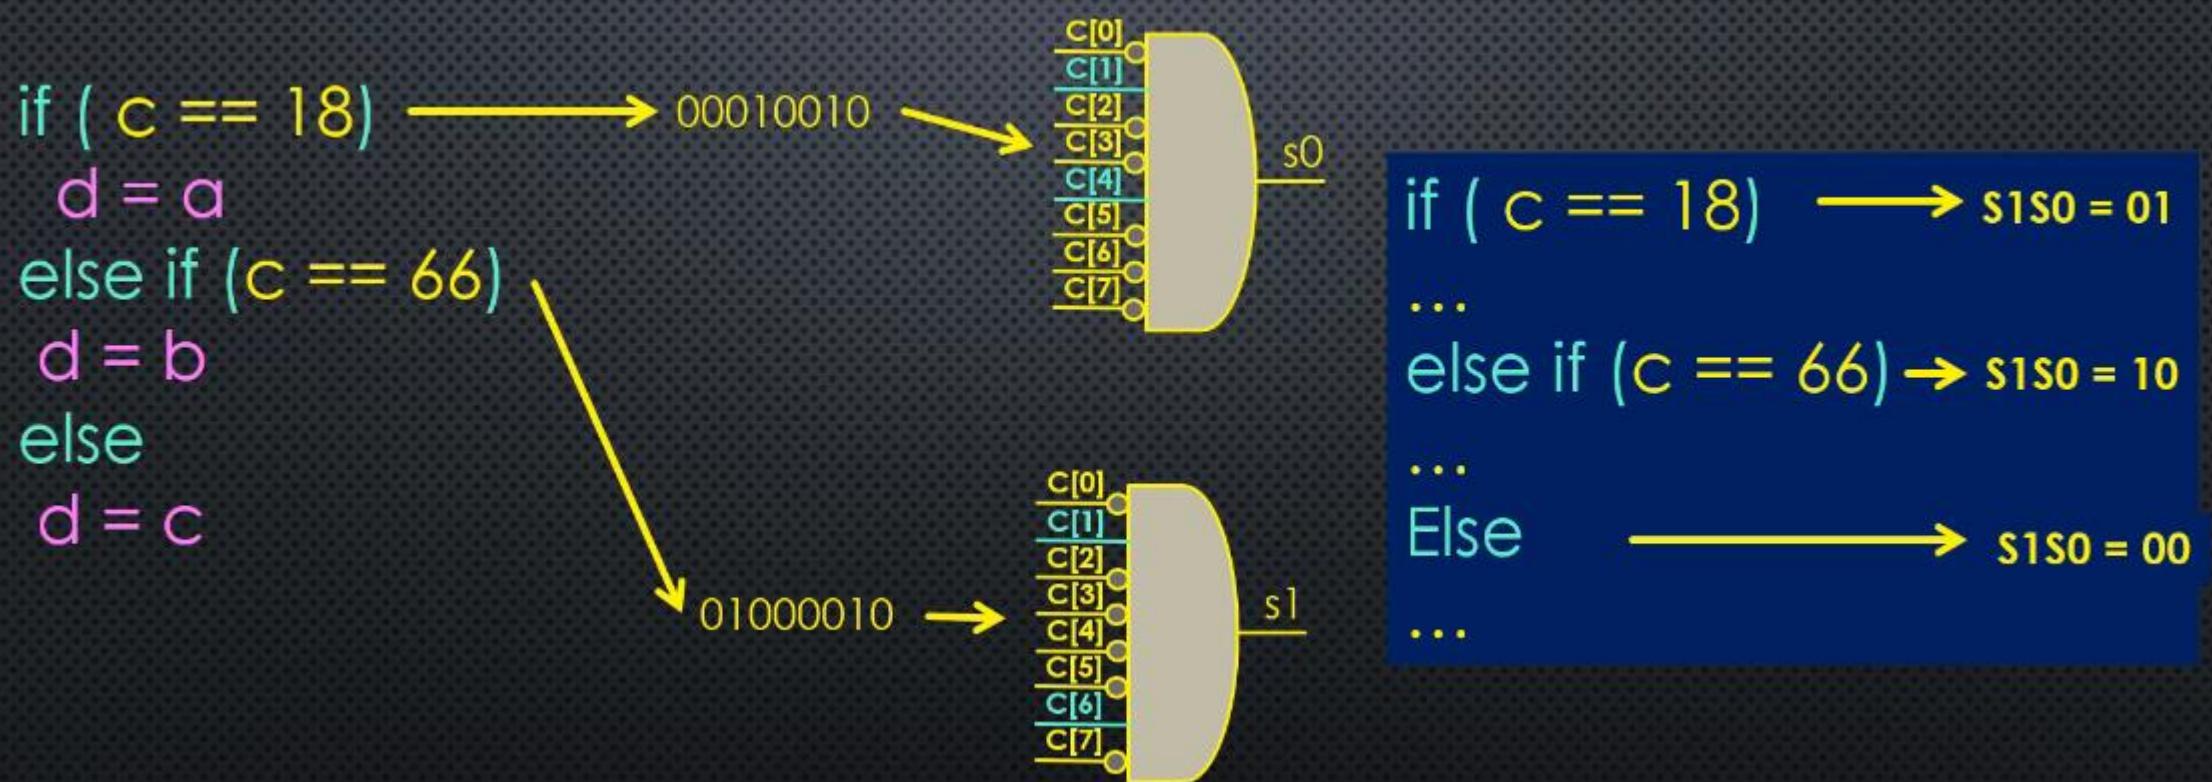

# COMPLEX DECISION MAKING

a, b, c and d have 8 bits

```
if ( c == 18)
    d = a
else if (c == 66)
    d = b
else
    d = c
```

# COMPLEX DECISION MAKING

# COMPLEX DECISION MAKING

a, b, and c have 8 bits

if ( c == 18) → S1S0 = 01

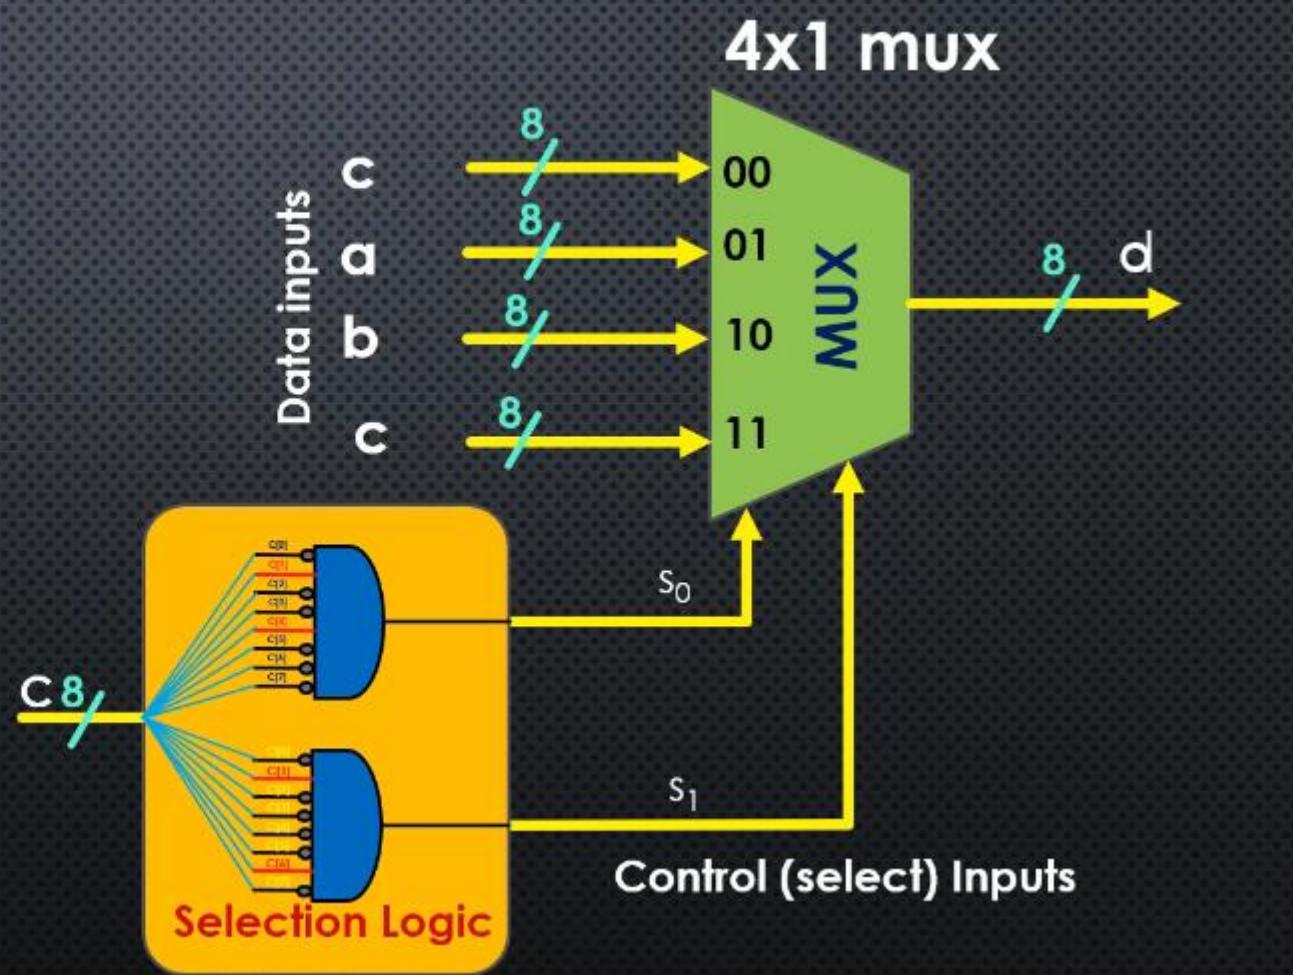

d = a

else if (c == 66) → S1S0 = 10

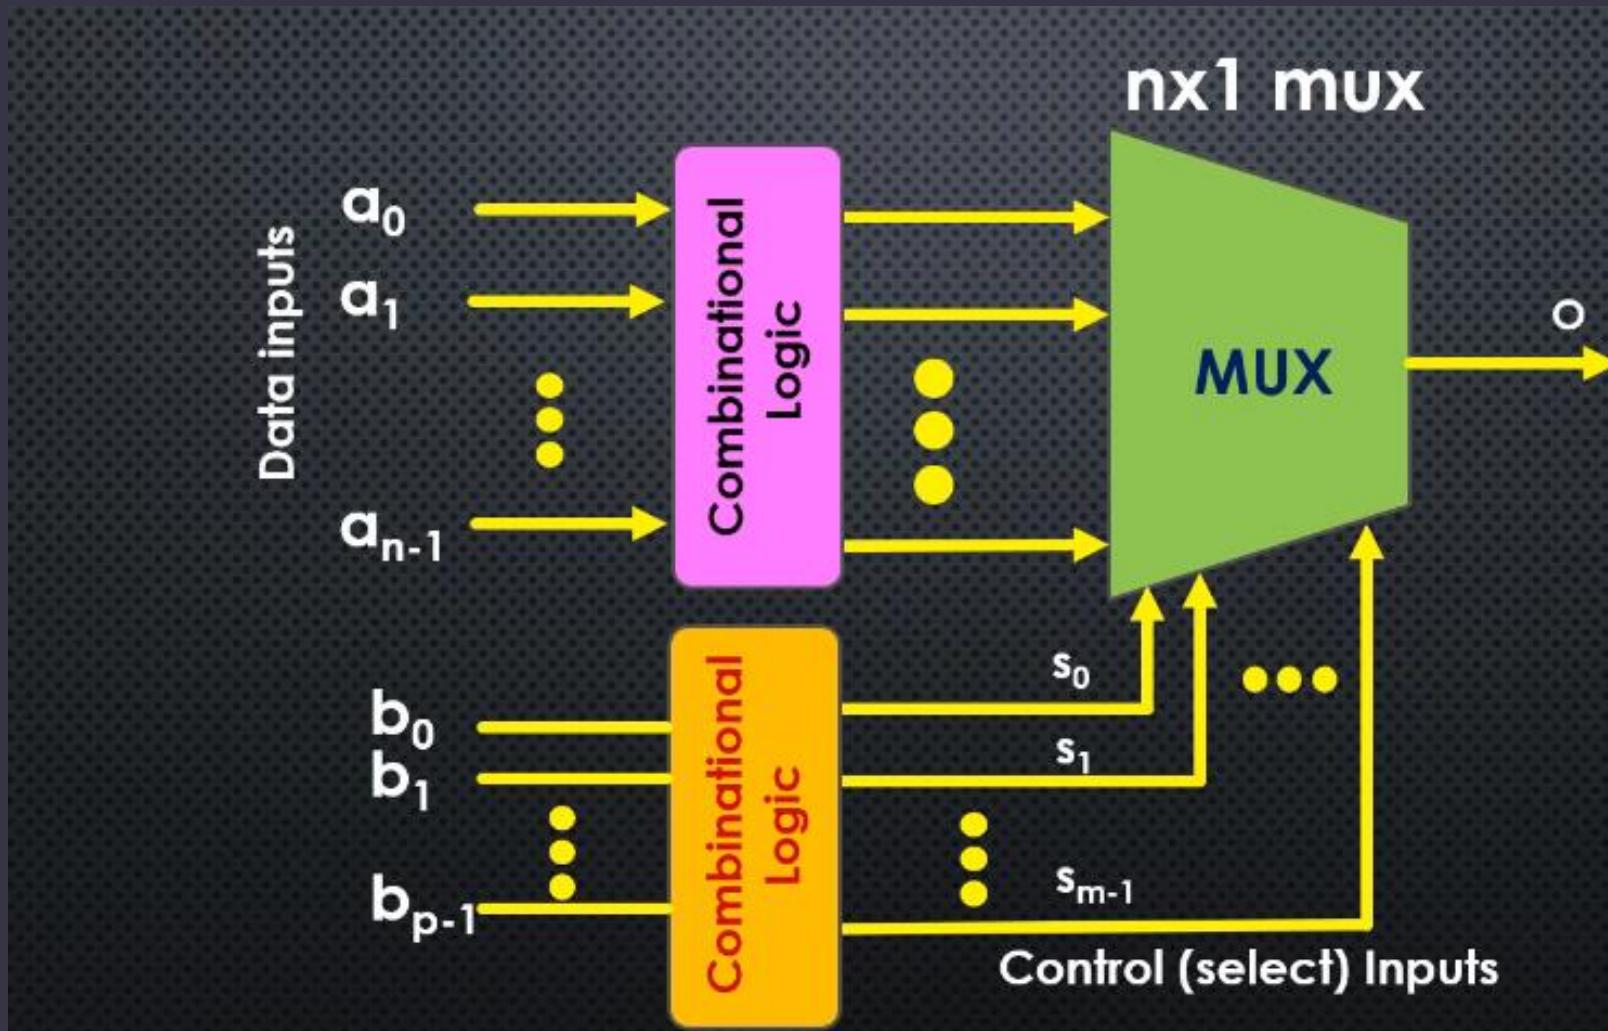

d = b

else → S1S0 = 00

d = c

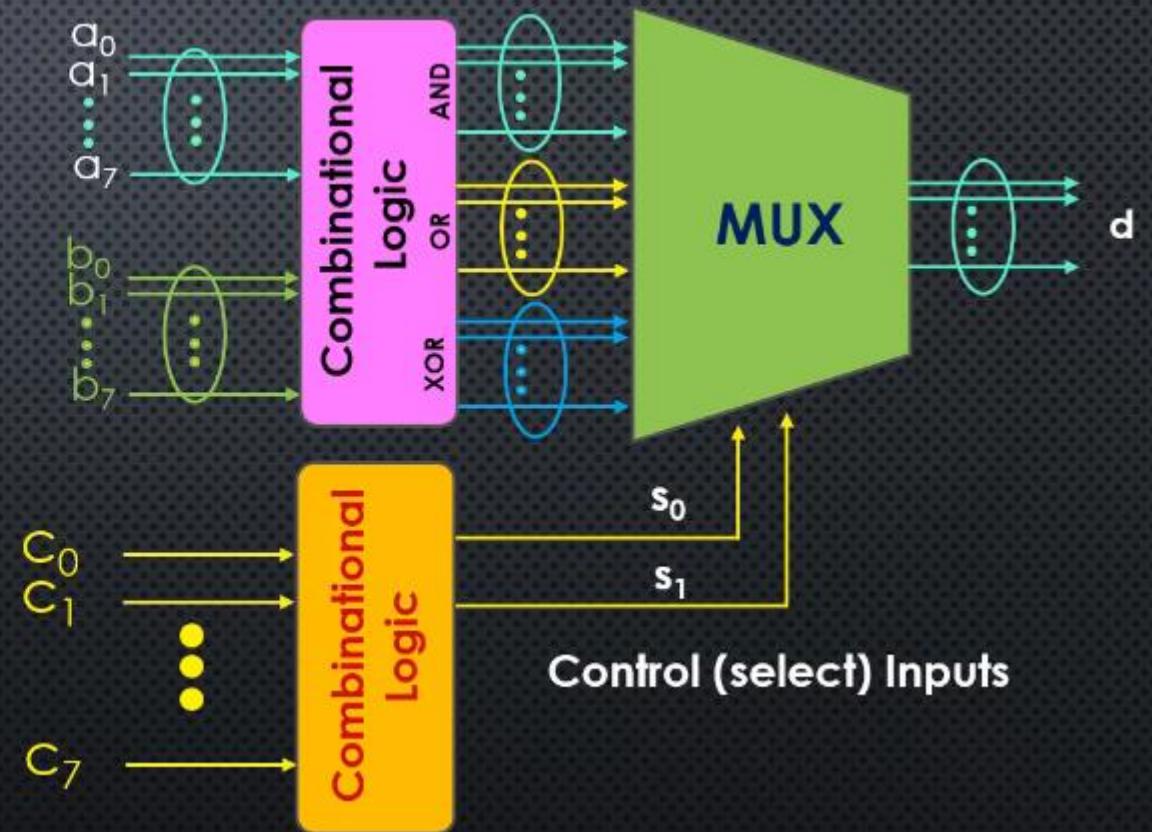

# COMPLEX DATA PREPARATION (GENERAL CASE 3)

# COMPLEX DATA PREPARATION EXAMPLE

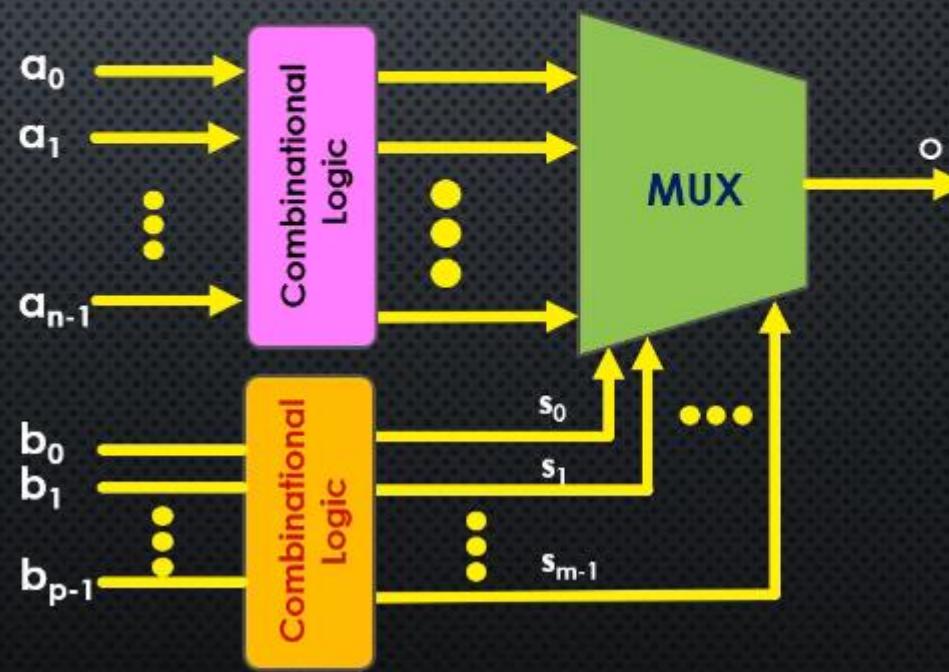

a, b, c and d have 8 bits

```
if ( c == 18)
    d = a & b
else if (c == 66)
    d = a | b
else
    d = a ^ b
```

# SUMMARY

A decision-making process can be implemented by a mux and two combinational circuits feeding the mux data and control inputs.

# ASSIGNMENT Q

**What is the hardware structure that implements this decision-making process?**

```
if ( c < 18)
    d = a & b
else if (c > 20)
    d = a | b
else
    d = a ^ b
```

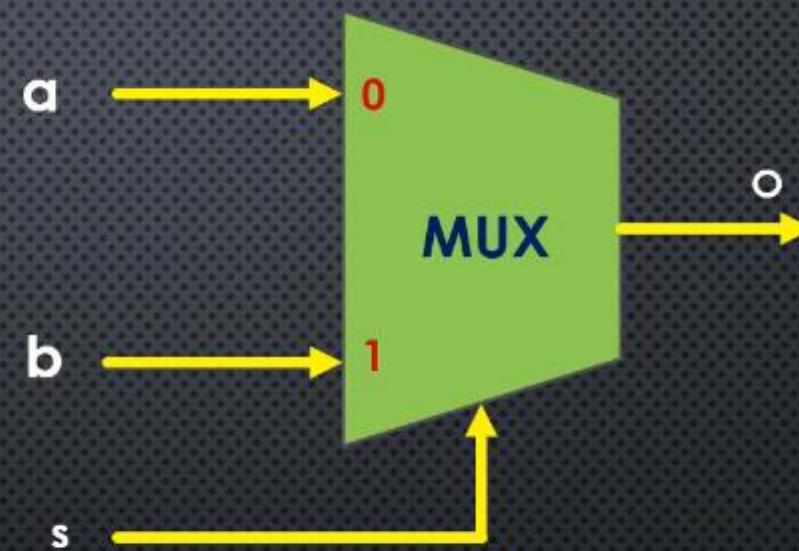

# MULTIPLEXER-HLS

Lecture – 4-Data type

# MULTIPLEXER IN HLS

Ternary Operator (`?:`)

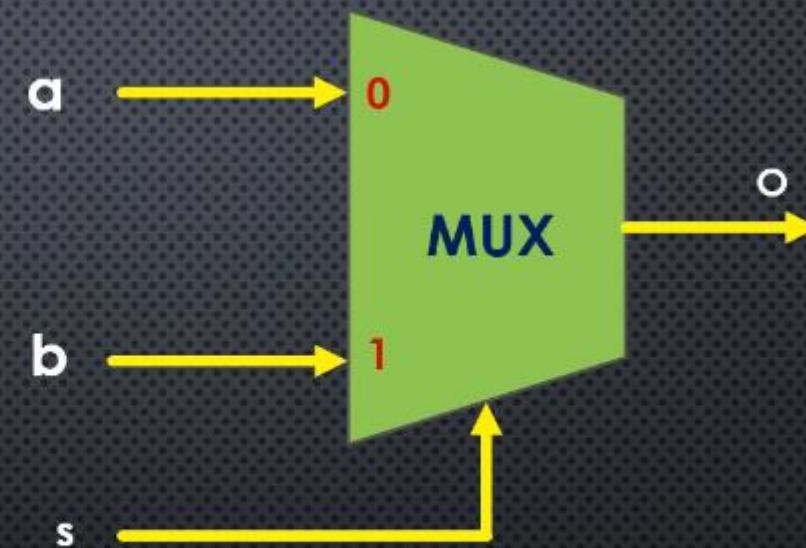

```
O = (s == 0)? a : b;
```

# MULTIPLEXER IN HLS

If-else comparison

```
if (s == 0)
    O = a;
else
    O = b;
```

# NOTE

```
if (s == 0)  
    O = a;
```

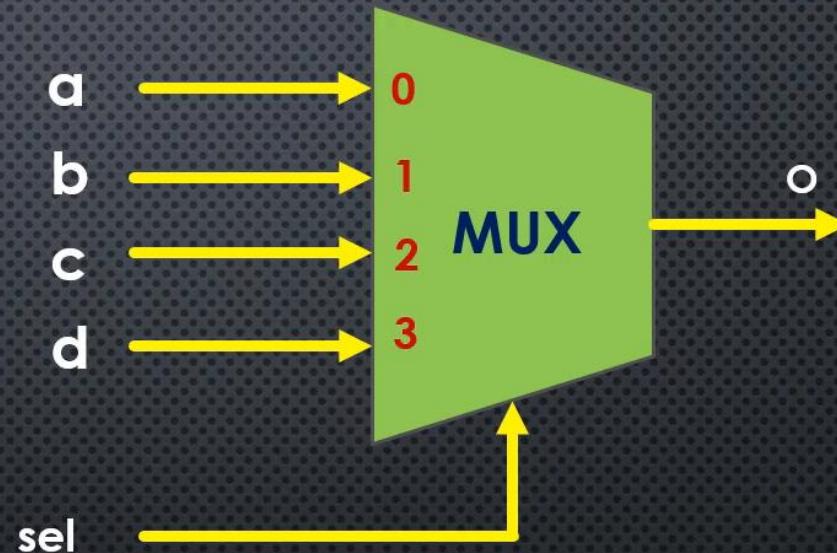

```
if (s == 0)  
    O = a;  
else  
    O = O;
```

In both cases we should keep track  
of previous value on the output O

# MULTIPLEXER IN HLS

## Switch-Case

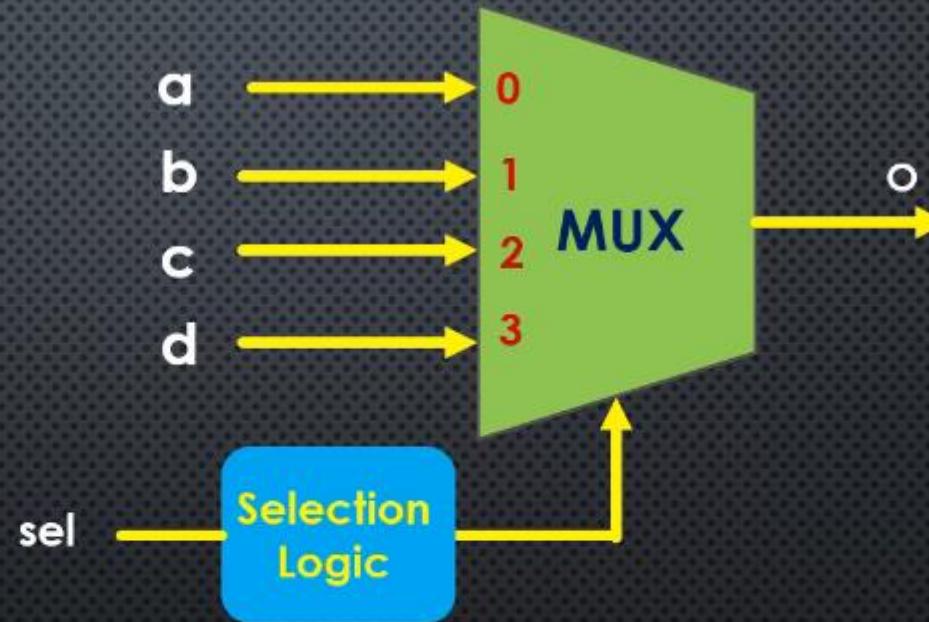

```
ap_int<2> sel;  
...  
switch (sel) {  
case 0:  
    O = a;  
    break;  
case 1:  
    O = b;  
    break;  
case 2:  
    O = c;  
    break;  
case 3:  
    O = d;  
    break;  
}
```

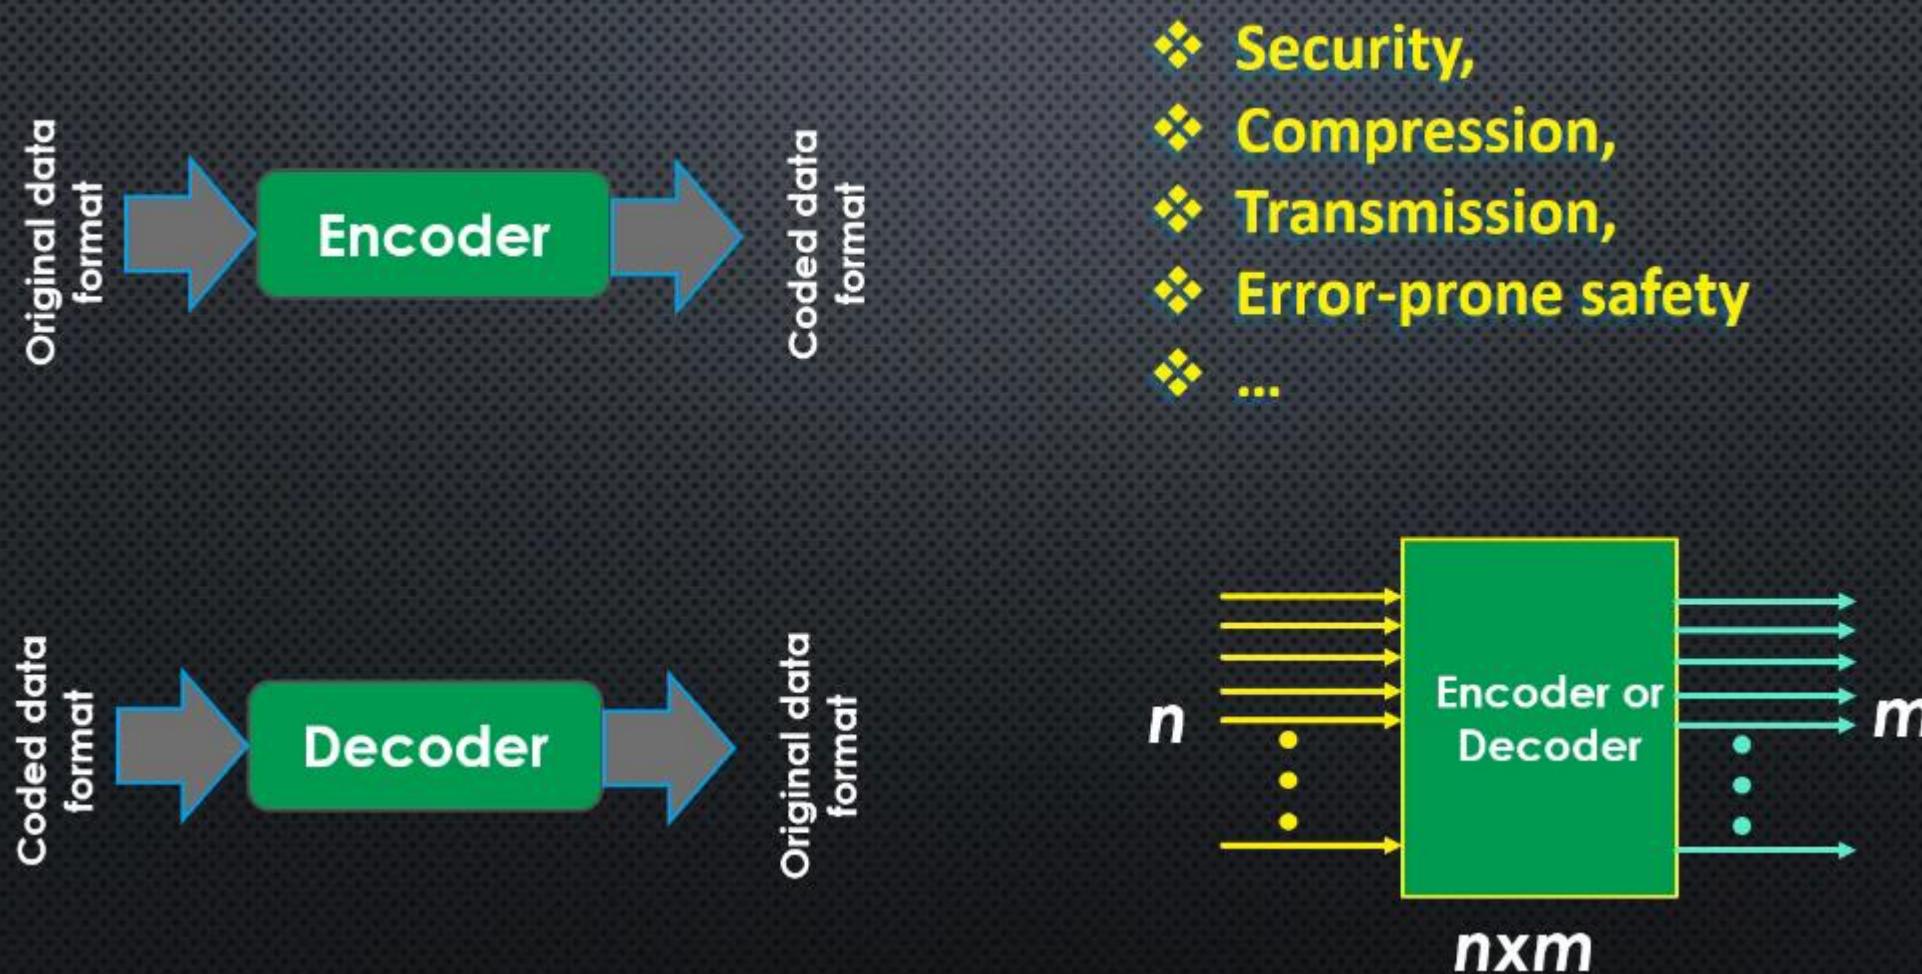

# MULTIPLEXER IN HLS (SWITCH-CASE)

## Switch-Case

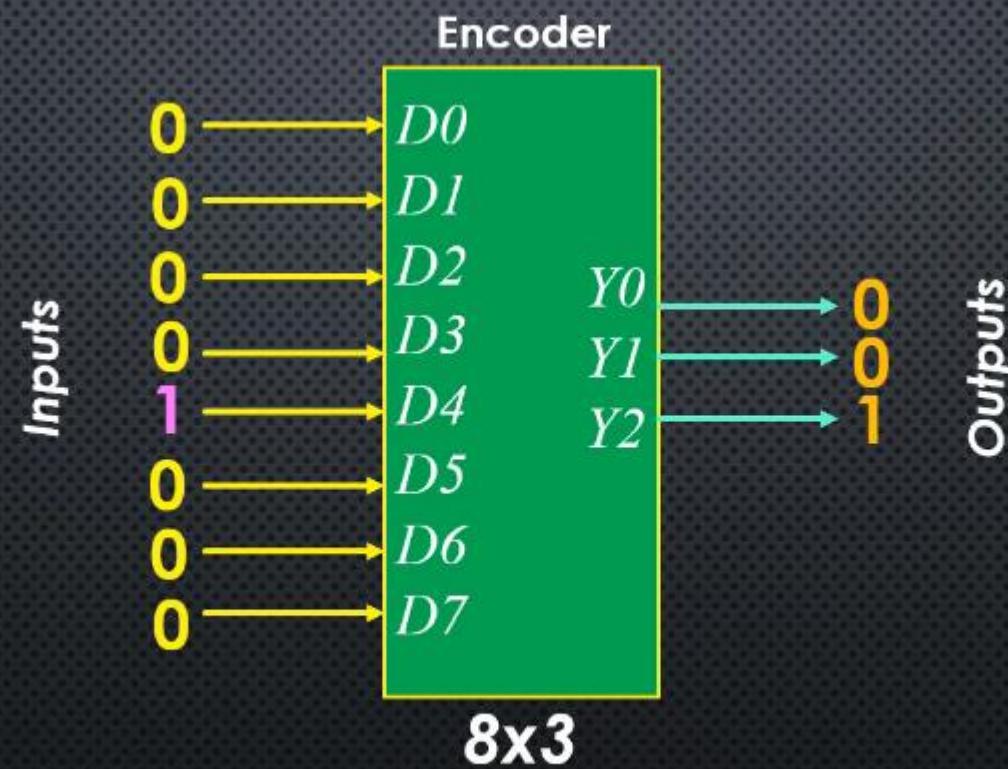

```
ap_int<8> sel;

# DECODER HARDWARE AFTER HLS SYNTHESIS

# ASSIGNMENT Q

**Use a switch-case statement in HLS to describe an 8 by 3 encoder circuit.**

# MULTIPLEXER-EXAMPLE

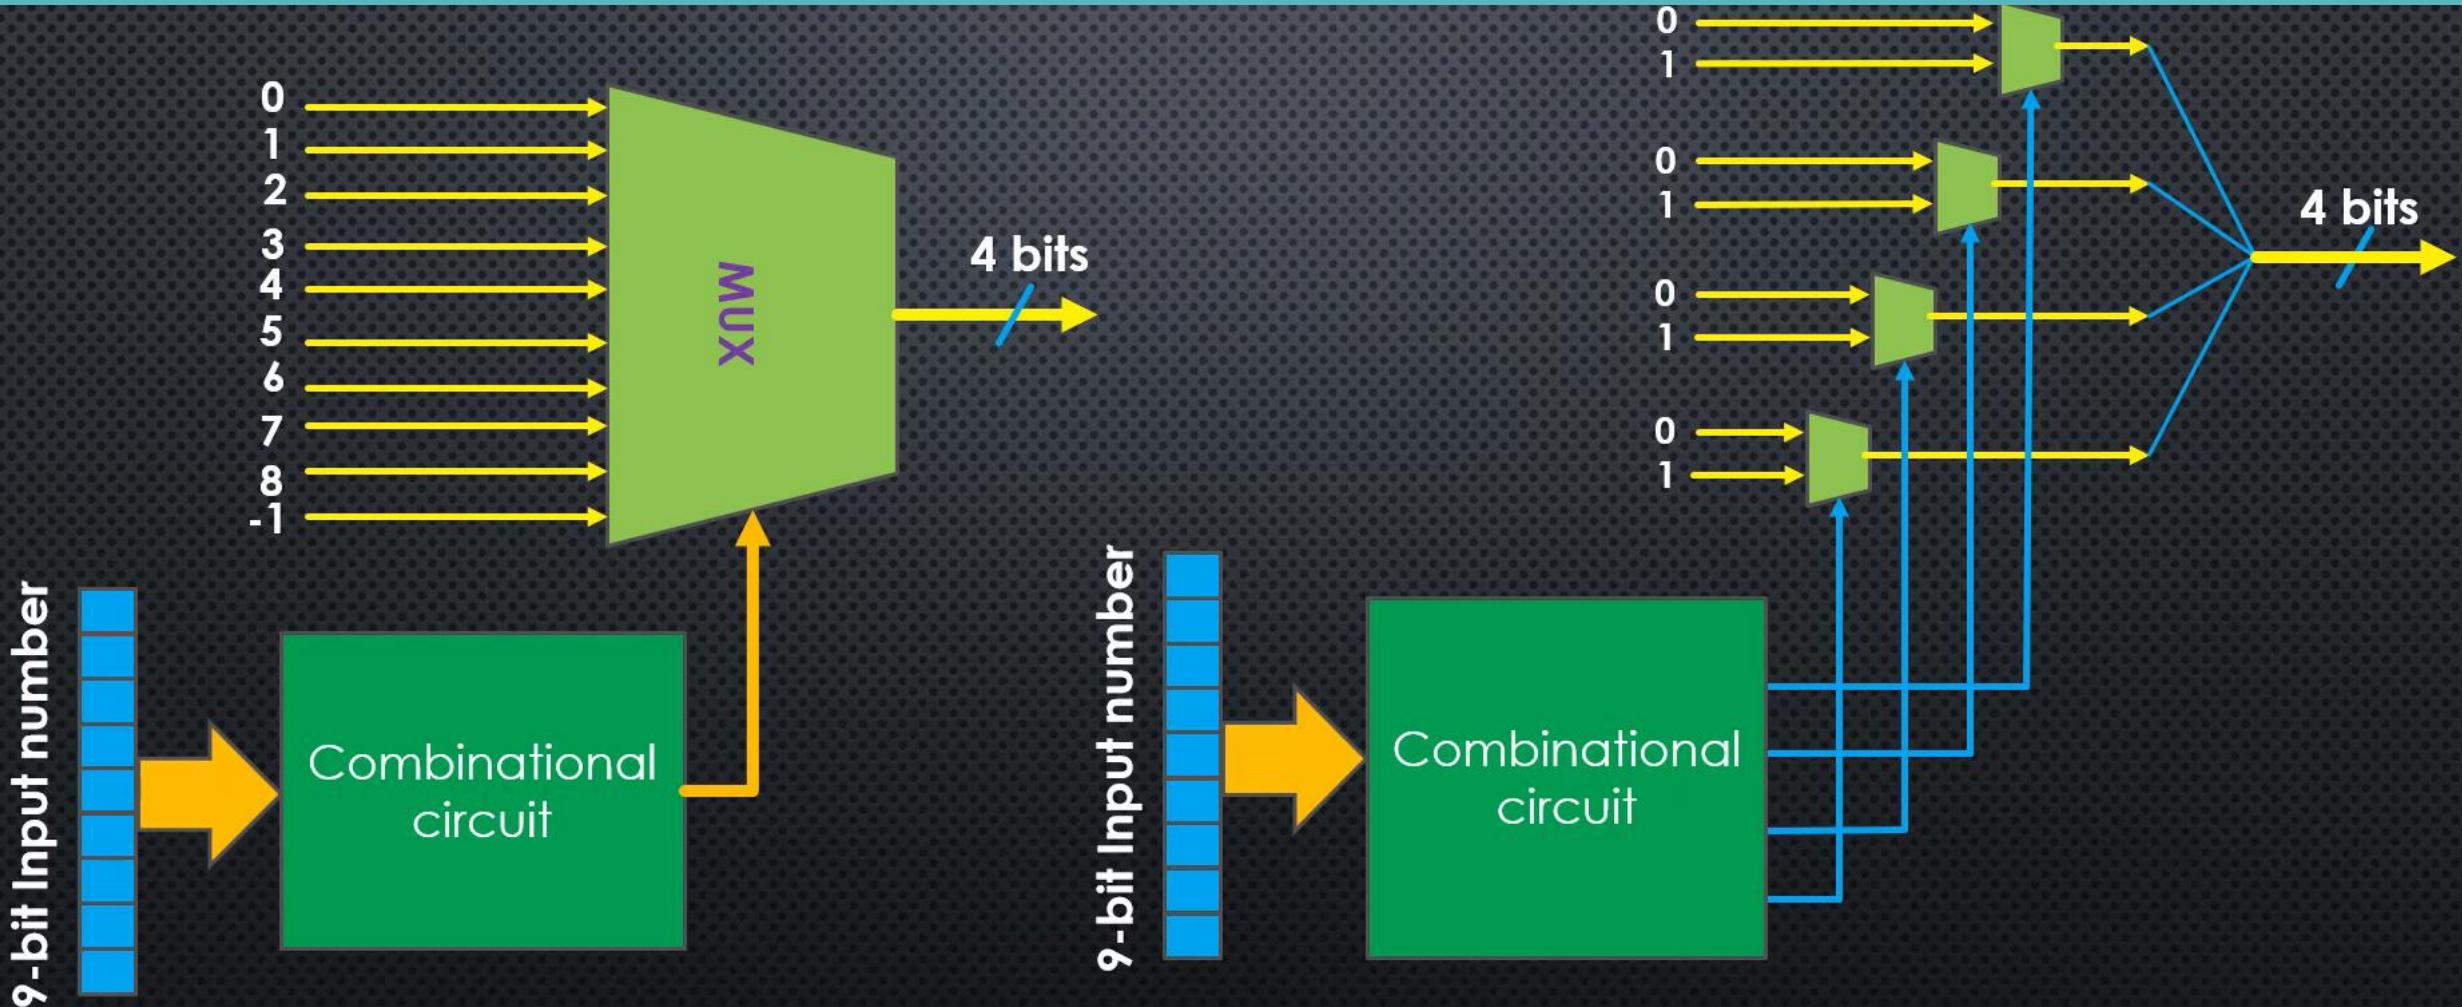

Lecture – 5

# LEADING ONE: DEFINITION

Design a combinational Logic circuits the returns the position of the leading one in an input 9-bit number

# LEADING ONE: LOGIC

# LEADING ONE: HLS

```
ap_int<5> find_leading_one(ap_uint<9> a) {  
    ap_int<5> index;  
  
    if (a[8] == 1) {  
        index = 8;  
    } elseif (a[7] == 1) {  
        index = 7;  
    } elseif (a[6] == 1) {  
        index = 6;  
    } elseif (a[5] == 1) {  
        index = 5;  
    } elseif (a[4] == 1) {  
        index = 4;
```

```
} elseif (a[3] == 1) {  
    index = 3;  
} elseif (a[2] == 1) {  
    index = 2;  
} elseif (a[1] == 1) {  
    index = 1;  
} elseif (a[0] == 1) {  
    index = 0;  
} else {  
    index = -1;  
}  
return index;
```

# ASSIGNMENT Q

This code implements a 4x2 encoder; its structure is very similar to the leading-one example. Find the missing numbers that determined by red question marks.

```
ap_int<?> encoder4x2(ap_uint<?> a) {  
    ap_int<?> code;  
  
    if (a[?] == 1) {  
        code = 3;  
    } elseif (a[?] == 1) {  
        code = 2;  
    } elseif (a[?] == 1) {  
        code = 1;  
    } else {  
        code = 0;  
    }  
  
    return code;  
}
